December 12, 2001

*Sciences International, Inc.*

# Purpose

- ❖ Develop a framework for conducting an exposure assessment for the VCCEP
- ❖ Illustrate the framework with an example exposure assessment
- ❖ Illustrate approaches to the VCCEP and the flexibility required to accommodate different chemicals and sponsors

# Essential Characteristics of a the Tier 1 Exposure Assessment

- ❖ Open and transparent
- ❖ Impose meaningful order on vast landscape of consideration (e.g., pathways, receptor groups, etc.)
- ❖ Preserve the integrity of the data
- ❖ Include all key factors in a way that inform exposure assessment (e.g., consideration of toxicity data)
- ❖ Focus on most significant pathways and receptor groups

# Parts of Framework

- ❖ Part 1 - Selection of exposure scenarios
  - Process by which exposure scenarios are selected for quantitative analysis
- ❖ Part 2 - Exposure assessment
  - Estimation of exposures for scenarios developed in Part 1

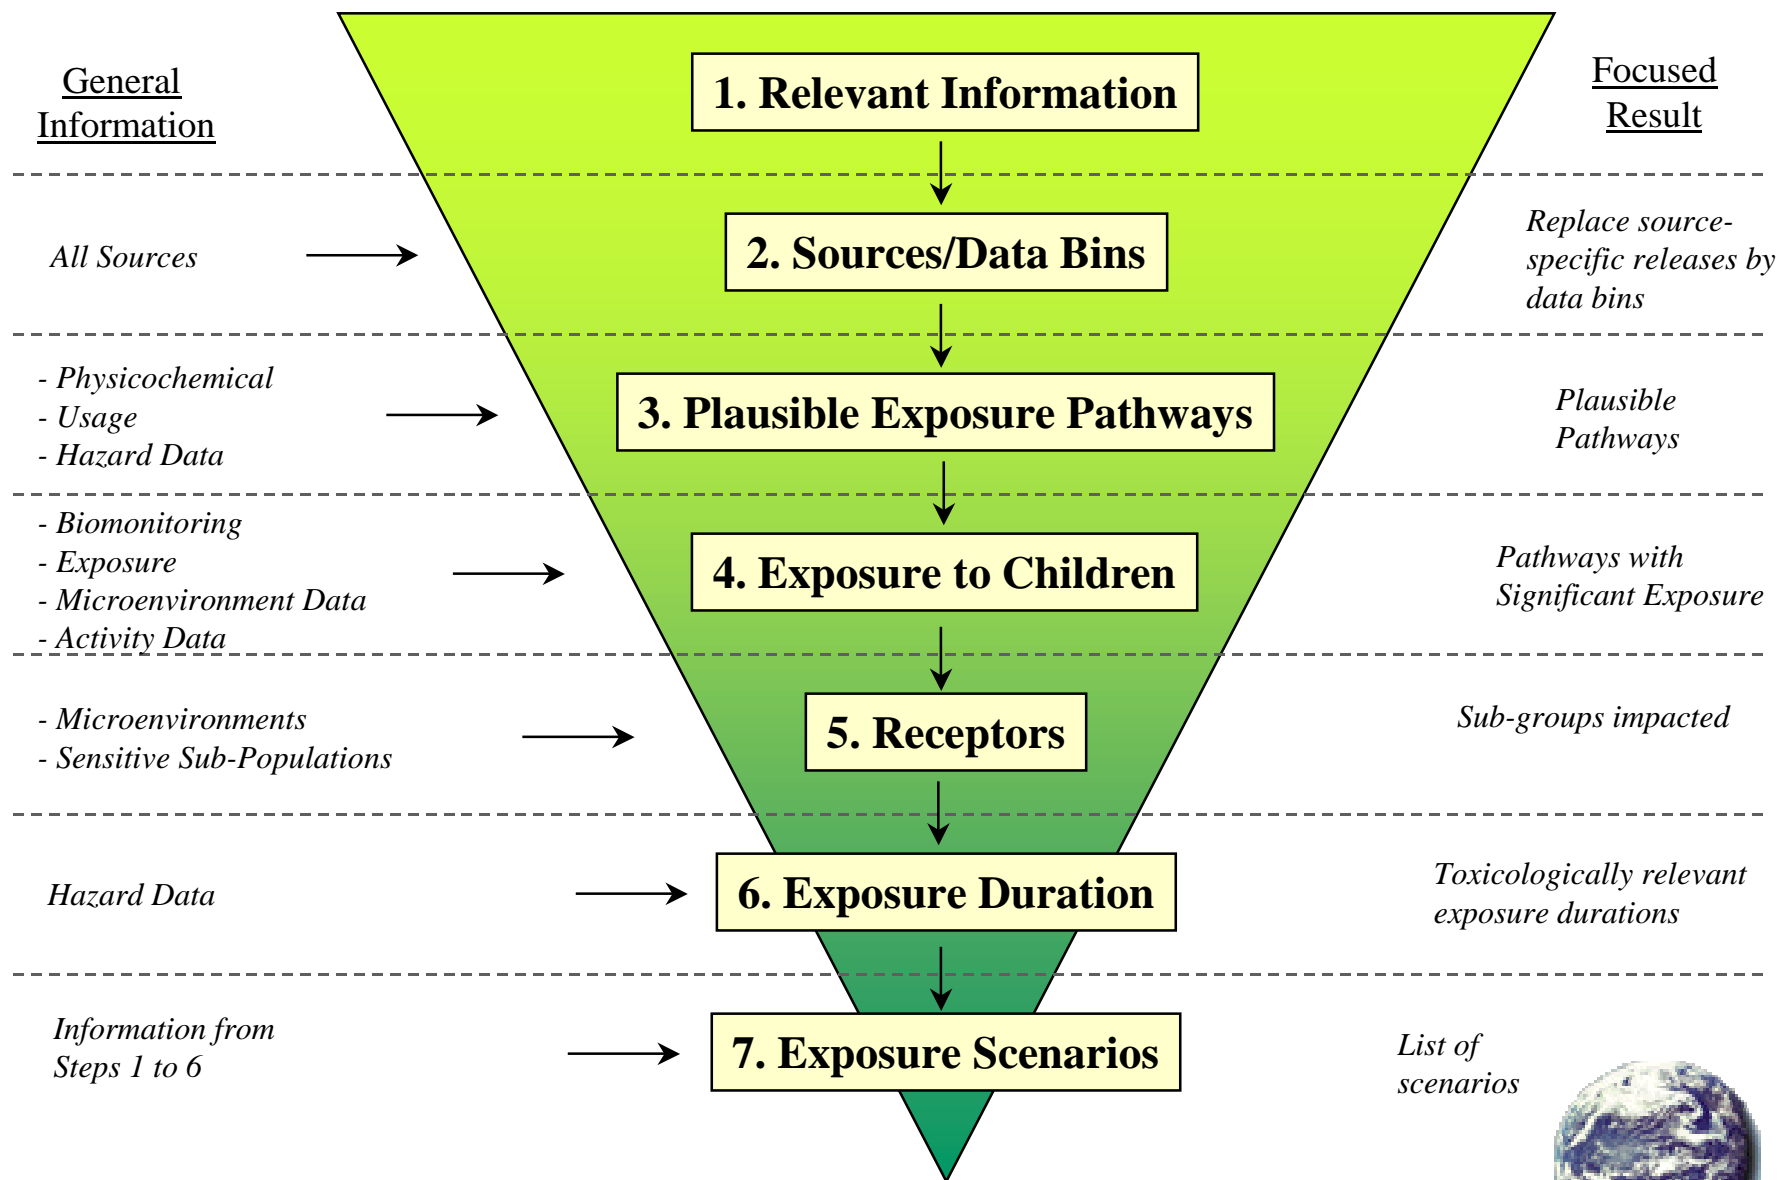

# What is the Framework

- ❖ The framework describes a process to systematically organize and evaluate the universe of all possible exposure sources and pathways to efficiently and effectively derive specific exposure scenarios necessary for a screening level exposure assessment.
- ❖ The exposure scenarios are used to develop a quantitative assessment of exposures for the receptors of concern.

# Part 1. Framework for Selection of Exposure Scenarios

# Part 1. Framework for Selection of Exposure Scenarios

- ❖ Step 1 - Assemble relevant information: includes production volumes; manufacturing and processing release amounts; industrial, institutional, and consumer uses of the product; outside the chain of commerce sources; disposal amounts; physicochemical properties; environmental fate properties; hazard data; and exposure data
  - Some information for chemical may not be available to sponsor
- ❖ Step 2 - Organization of sources into data bins: grouping of separate sources that contribute to same exposure pathway

# Part 1. Framework for Selection of Exposure Scenarios

- ❖ Step 3 - Determination of plausible exposure pathways: develop list of plausible pathways based on usage profile and physicochemical properties
- ❖ Step 4 - Inclusion of pathways with significant exposure to children: determination of pathways relevant to children
- ❖ Step 5 - Consideration of receptors: determining populations and subpopulations that may be exposed

# Part 1. Framework for Selection of Exposure Scenarios

- ❖ Step 6 - Consideration of exposure durations:  
consideration of appropriate exposure durations based on toxicity
- ❖ Step 7 - Development of exposure scenarios: final list of scenarios to consider based on steps 1 through 6

# Part 2 - Exposure Assessment

- ❖ Screening-level exposure and risk assessment for exposure scenarios
- ❖ Refined exposure and risk assessment for exposure scenarios, if necessary
- ❖ Aggregate assessment
  - All exposure estimates need to be conservative, and be biased to err on the side of public safety

# Refining the Assessment

# Case Study

- ❖ Based on hypothetical chemical called Seussium grinchate (SGA)
- ❖ SGA has the following uses:
  - Solvent in the manufacture of carpets
  - Component of various household cleaners
  - Solvent used in food extraction
  - Chemical intermediate

# Step 1 - Assembly of Information for Exposure Assessment

- ❖ Manufacturing and usage data:
  - Produced in five manufacturing plants nationwide
  - Total production volume of 2,200 tons per year (tpy)
  - Air emissions of 88 tpy and water discharges of 2.2 tpy
  - Largest facility is operated by Whoville Industries in Whoville.
  - Also used in three plants that produce carpet, six plants that produce household cleaners, and as an intermediate for chemical processes at two facilities.

# Information for Exposure Assessment (continued)

- ❖ Physicochemical properties and environmental fate
  - Slightly volatile (vapor pressure of 0.1 mmHg)
  - Low persistence in water or soil (2.5 day aerobic biodegradation half-life)
  - Low persistence in air (4 day half-life for reaction with hydroxyl radicals)

# Information for Exposure Assessment (continued)

- ❖ Existing exposure and biomonitoring data
  - In EPA's TEAM study, SGA was detected in most of several thousand indoor air measurements
  - In FDA's Total Diet Study (TDS), SGA was detected in 63% of green eggs, 72% of hams, and 34% of red wine samples
  - In CDCP's NHANES study, SGA was detected in 23% of human blood samples at trace quantities

# Hazard Summary

- ❖ Low acute toxicity
- ❖ Neurotoxicity by ingestion
- ❖ Respiratory irritation by inhalation
- ❖ Developmental effects
- ❖ Carcinogen by inhalation, but not ingestion
- ❖ Not an allergen, sensitizer, reproductive toxicant, or immunotoxicant

# Step 2 - Organization of Sources into Data Bins

- ❖ All household cleaning products and carpets are aggregated into a data bin for the estimation of indoor air exposure
  - Therefore, these sources do not need to be considered separately

# Step 3 - Determination of Plausible Exposure Pathways

- ❖ Inhalation of residential indoor air due to indoor sources
- ❖ Inhalation of ambient air due to manufacturing facilities
- ❖ Inhalation of volatilized SGA for children breathing very close to carpet surfaces
- ❖ Ingestion of food due to its detection in green eggs and ham, and in red wine
- ❖ Ingestion of breast milk by infants, due to detections in blood samples

# Step 3 - Determination of Plausible Exposure Pathways (continued)

- ❖ Ingestion of drinking water
- ❖ Ingestion of SGA by mouthing of toys and other objects from contact with carpet and residues from household cleaners
- ❖ Dermal contact with carpets, due to SGA use on carpets and because infants frequently play on carpet
- ❖ Dermal contact for household cleaner usage
- ❖ Occupational exposure to pregnant women, due to monitoring data in the Whoville facility and because SGA has developmental effects

# Step 4 - Inclusion of Pathways with Significant Exposure to Children

- ❖ SGA was never detected in EPA's National Drinking Water Contaminant Database (over 2,000 samples)
  - Detection limit of 0.01 µg/L
  - Wastewater removal efficiency of 99%
  - Rapid biodegradation in water
- ❖ SGA detected in green eggs, ham, and wine. But children do not generally consume wine
- ❖ Dermal contact exposure for household cleaner usage considerably less than dermal contact with carpet

# Step 5 - Consideration of Receptors

Age Range	Gender	Body Weight (kg)	Inhalation Rate (m <sup>3</sup> /day)
Infants	Both	7.1	4.5
1-2	Both	12.3	6.8
3-5	Both	17.5	8.3
6-8	Both	25.2	10
9-11	Male	35.9	14
	Female	36.6	13
12-14	Male	50.4	15
	Female	50.7	12
15-18	Male	66.5	17
	Female	66.0	12

Draft Children's Exposure Factor Handbook

*Sciences International, Inc.*

# Step 5 (continued) - Ratio of Inhalation Rate to Body Weight by Age

# **Step 5 - Consideration of Receptors: Geography (continued)**

- ❖ For ambient exposure, the subpopulation of children who live near the manufacturing plants must be considered

# Step 6 - Consideration of Exposure Durations

- ❖ Because SGA has a very low acute toxicity, only chronic and lifetime-average exposures need to be considered
- ❖ Because SGA is only carcinogenic via inhalation and not ingestion, lifetime-average exposures will only be calculated for inhalation pathways

# Step 7 - Development of Exposure Scenarios

Pathway	Chronic Exposure	Lifetime Exposure	Population of Concern	Significant Subpopulation
Inhalation of ambient air near plants, plus exposure to SGA from indoor sources	X	X	Children	People living near production or manufacturing plants
Ingestion of food	X		Children	
Ingestion of breast milk	X		Children	Infants
Dermal contact with carpet	X		Children	Infants
Occupational exposure	X		Pregnant women and offspring	Pregnant women working at production facilities

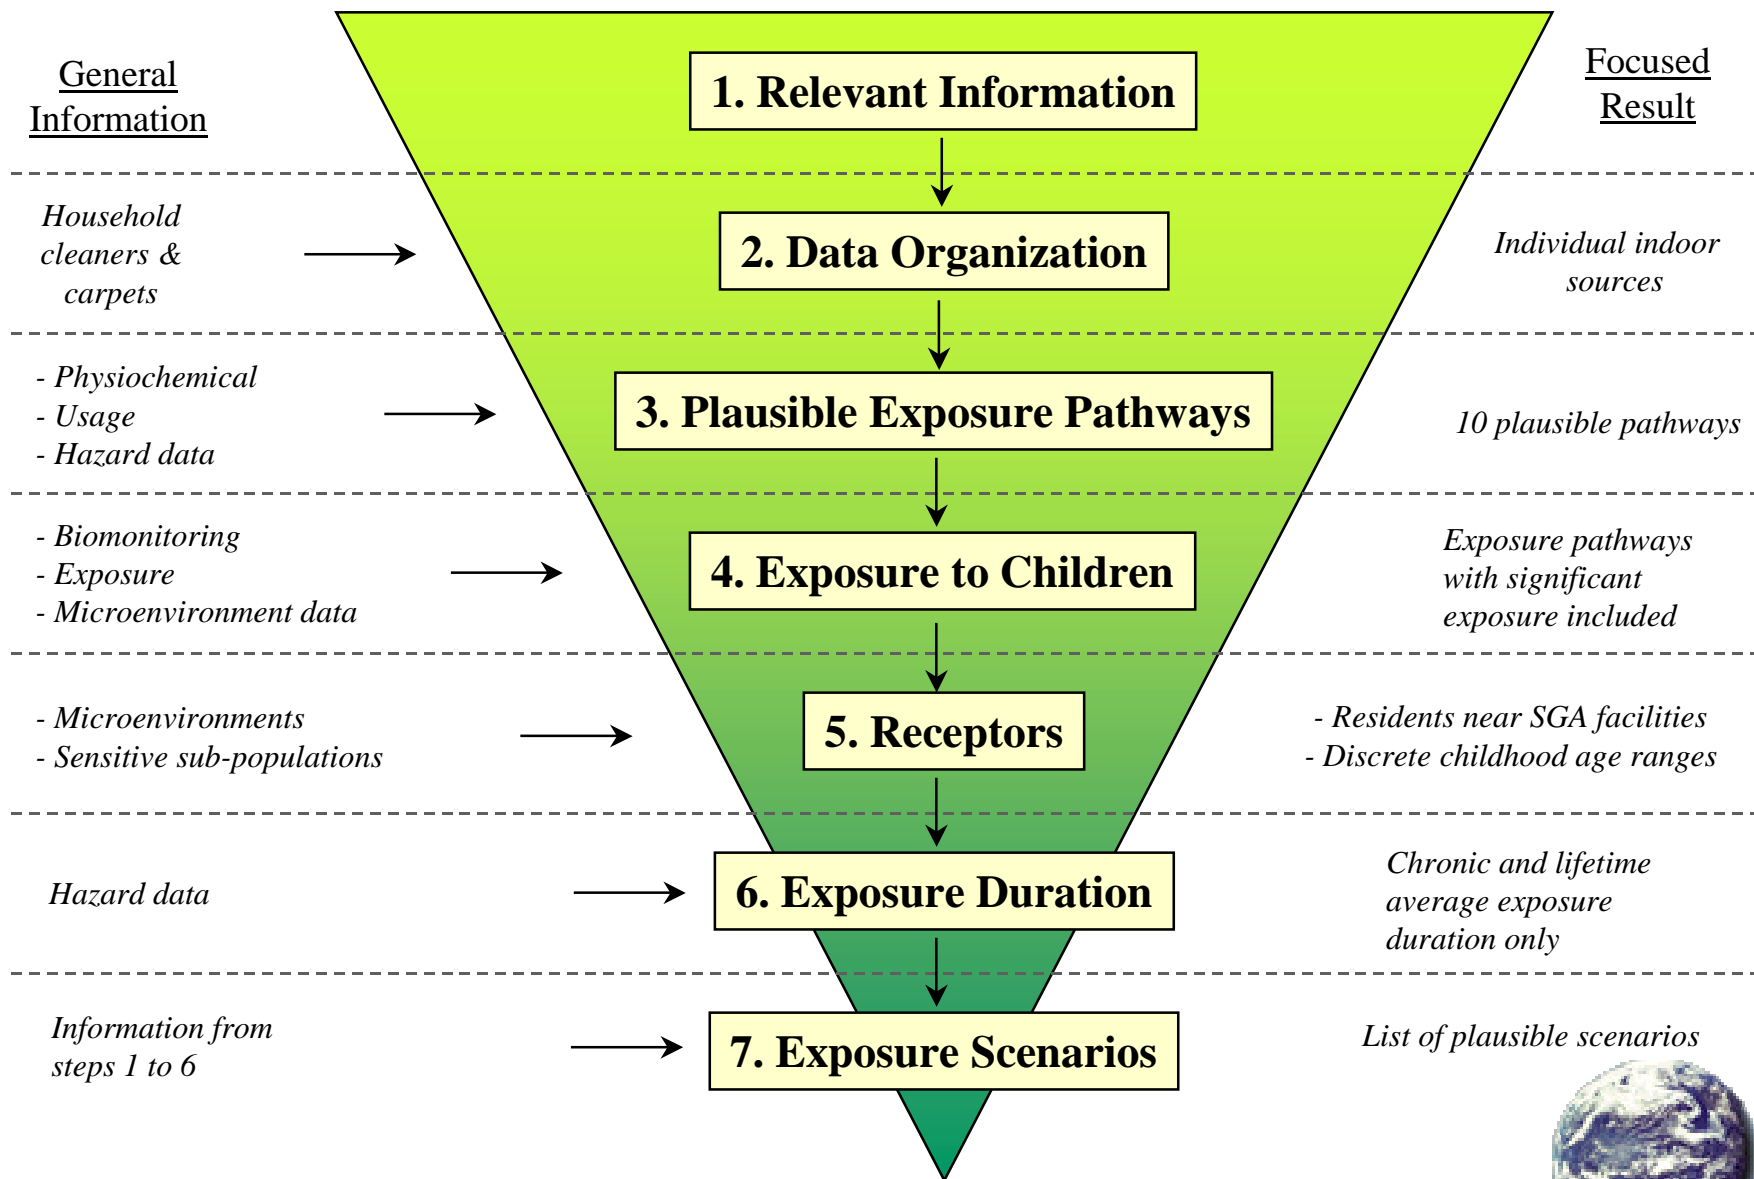

# Exposure Assessment Results

- ❖ Screening-level exposure estimates err on the side of public safety:
  - Identification of highly exposed subpopulations
  - Use of upper-bound exposure estimates
  - Conservative assumptions about activity patterns (i.e., duration of exposures)
  - For food exposure, conservative assumptions about food intake

# Application of Framework to Case Study

# Exposure Assessment for Case Study

- ❖ Report includes a detailed exposure assessment for the five exposure scenarios
- ❖ For each scenario, a risk assessment is included to illustrate the tiered process of exposure assessment
- ❖ An aggregate assessment is included for all pathways
- ❖ For this presentation, the air inhalation pathway exposure pathway was chosen as an example illustration

# Inhalation Exposure for Residents Near Production Facilities

## ❖ *Screening-Level Exposure Assessment*

### – Ambient Air

- ◆ Dispersion modeling for the SGA manufacturing plant in Whoville, which has the highest releases and shortest distance to fenceline
- ◆ SCREEN3 air dispersion model (very conservative and simple)
- ◆ Emission rate and stack dimensions provided by facility
- ◆ Maximum off-site 24-hour air concentration predicted to be  $10 \mu\text{g}/\text{m}^3$ .

# Inhalation Exposure for Residents Near Production Facilities

## ❖ *Screening-Level Exposure Assessment*

### – Indoor Air

- ◆ SGA assumed to infiltrate into residences in a 1:1 ratio
- ◆ Additional SGA from indoor sources. Based on TEAM study, a large measurement program of indoor air concentrations in U.S., contribution is  $0.02 \mu\text{g}/\text{m}^3$ .

### – Combined Indoor and Outdoor Exposure

- ◆ Approximately  $10 \mu\text{g}/\text{m}^3$ , predominantly from outdoors

# Inhalation Exposure for Residents Near Production Facilities

## ❖ *Screening Level Risk Characterization*

### – Noncancer Risk

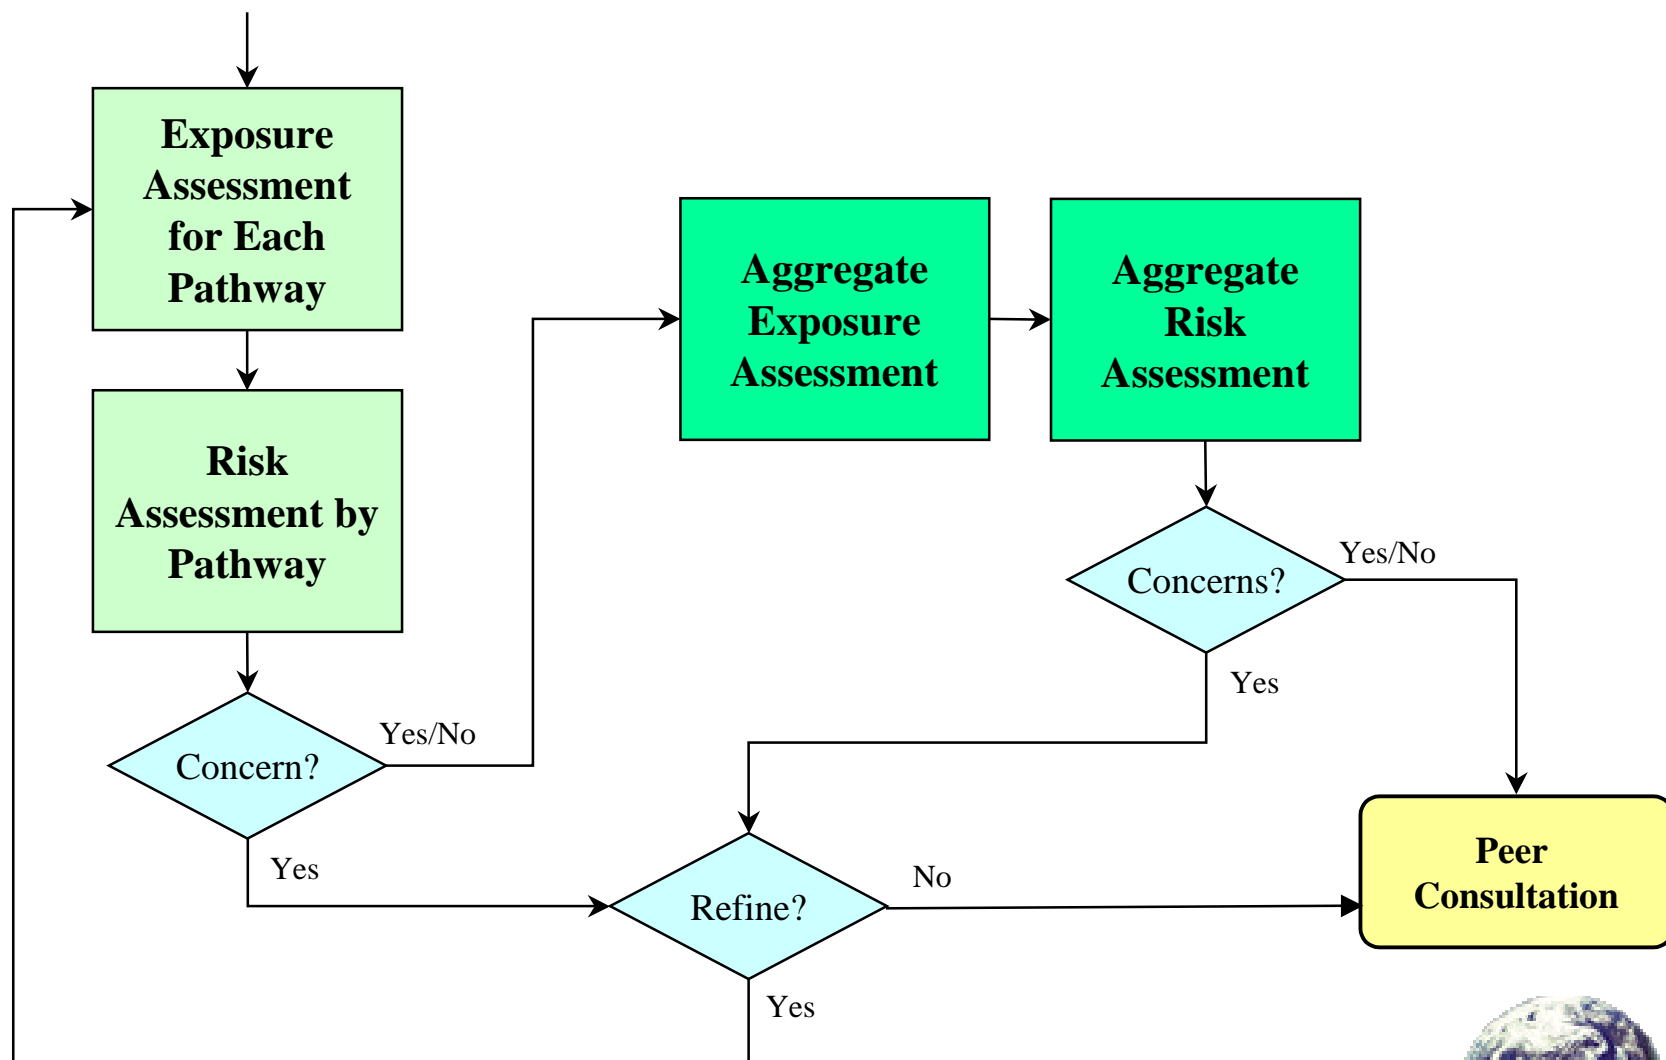

- ◆ With RfC of 1 mg/m<sup>3</sup> and exposure concentration of 10 µg/m<sup>3</sup>, hazard index is 0.01 or well below any concern

### – Cancer Risk

- ◆ Cancer Risk = Unit Risk (5x10<sup>-6</sup> per µg/m<sup>3</sup>) \*  
Concentration (10 µg/m<sup>3</sup>) = 5x10<sup>-5</sup>
- ◆ Above level of concern; therefore, a refined assessment was conducted.

# Refining the Assessment

# Inhalation Exposure for Residents Near Production Facilities

## ❖ *Refined Exposure Assessment*

- Additional resources were expended to collect more data and use a more accurate and sophisticated model
  - ◆ ISCST3, a more sophisticated dispersion model is used
  - ◆ Five years of meteorological data from nearest National Weather Service station
  - ◆ Survey of land use around Whoville facility conducted; locations of residences and schools determined
  - ◆ Assumptions about time spent indoors and outdoors

# Map of Whoville Facility

# Inhalation Exposure for Residents Near Production Facilities

## ❖ *Refined Exposure Assessment*

- The more accurate and realistic exposure assessment was  $0.04 \mu\text{g}/\text{m}^3$  compared to  $10 \mu\text{g}/\text{m}^3$  from screening level assessment.
- Total exposure (indoor + outdoor) is  $0.06 \mu\text{g}/\text{m}^3$

## ❖ *Refined Risk Characterization*

- Cancer risk is well below  $10^{-5}$

# Aggregate Assessment

## ❖ *Exposure Assessment*

- Considered combined exposure from inhalation (assumed 100 percent absorption), ingestion of food, ingestion of breast milk, and dermal contact with carpet
- Exposure ranges from 0.067 (15 to 18 year olds) to 0.16 mg/kg/day (infants)
- Dermal contact with carpet largest contributor for younger children, and food ingestion for older children

## ❖ *Risk Characterization*

- Exposures below RfD, no concerns

# Aggregate Exposure by Pathway: Dermal and Food (Inhalation and ingestion of breast milk are negligible)

# Summary of Methodologies and Lessons in Case Study

- ❖ Development of methodology to identify potential exposure pathways for a chemical
- ❖ Focus on pathways of primary concern
- ❖ Simple “check-the-box” methods are insufficient
- ❖ Development of methodologies to refine screening level assessment, if necessary (even if its not required)
  - Process may end at screening level or continue to a more refined level

# Summary of Methodologies and Lessons in Case Study

- ❖ Need to consider hazard data when doing exposure assessment
- ❖ End result must be completely open, transparent, and accountable
- ❖ Flexibility required to accommodate different chemicals and sponsors
